Attention: Ms. Melanie Horton, MCIP, RPP Property and Resource Manager

Dear Sirs:

Re: Hydrogeological Study
St. Marys Cement Inc. (Canada) Codrington Property
Part of Lots 32, 33 and 34, Concession 6
Township of Brighton
County of Northumberland, Ontario
File 051777.00

We are pleased to submit our final report for the above-noted project. The report provides the results of the Hydrogeological Study for the Codrington Property that is proposed to be operated as a sand and gravel pit above the groundwater table.

The results of the Hydrogeological Study, which include the data of the May 2008 monitoring event, indicates that the above water table pit development and operations will not impact local groundwater or surface water resources. Therefore, a Level 2 Hydrogeological Study is not required. A performance monitoring program is outlined in Section 4.0 of the report.

Thank you for the opportunity to complete the project. Please contact us if you have any questions.

Yours truly, JAGGER HIMS LIMITED

MEMORANDUM

TO:	Mr. Mike Le Breton, B.E.S. Mr. Amarjit Sandhu
COPY:	Ms. Melanie Horton, MCIP, RPP
FROM:	Jason Balsdon, P.Eng. Vyacheslav Magmedov, P.Geo.
DATE:	May 15, 2009
SUBJECT:	Hydrogeological Study St. Marys Cement Inc. (Canada) Codrington Property File 051777.00

Based on discussions between the MNR representative and CBM, which was held on May 8, 2009, it is understood that the groundwater performance monitoring program will be implemented as outlined in Section 4.0 of Jagger Hims Limited report during the Codrington Pit development.

This memorandum is an addendum to our report dated March 30, 2009 and does not affect the general summary/recommendations of the report. Please call if you have any questions.

VGM:lnc

EXECUTIVE SUMMARY

St. Marys Cement Inc. (Canada), known locally as CBM Aggregates, is proposing to submit a Category 3 application under the Aggregate Resources Act (ARA) and its associated Provincial Standards. Approval for the application will permit the establishment of an above water table pit on lands referred to as the "Codrington Property," located east of the Village of Codrington, approximately 12 km north of Brighton. The property includes the land south of the Ontario Hydro Powerlines in Parts of Lot 32, 33, and 34, Concession 6 of the Township of Brighton (site).

To confirm the location of the seasonal high water level and to evaluate that the abovewater extraction would have no adverse effects on the local groundwater and surface water resources, a Hydrogeological Study was undertaken by Jagger Hims Limited to meet and exceed the Provincial requirements as established by the ARA Provincial Standards. In addition, this Hydrogeological Study also addressed the requirements of the Township of Brighton Official Plan with respect to hydrogeological (groundwater) and hydrological (surface water) issues.

A sand and gravel unit (Unit 2) occurs across the southern portion of the site and achieves a confirmed maximum thickness of about 25 m within the south-central portion of the site. Unit 2 was not detected within the northwestern portion of the site. A unit of sand with minor gravel (Unit 3) occurs below Unit 2 and also extends below the northwestern portion of the site. Silt to silty sand (Unit 1) occurs at surface within the northwestern portion of the site and was confirmed to increase in thickness toward the northwest to a depth of about 17 m. This Unit 1 was not detected within the southern and eastern portions of the site.

The site is located within a high area of land that forms a regional recharge area for dominantly confined aquifers in the surrounding lower lying areas. Most water wells are developed in the confined aquifers at a depth greater than 15 m below ground surface. The

quantity of water available for domestic water supply wells will not be negatively affected by the pit development as the recharge to the aquifer developed by the local water wells is predicted to increase. In addition, there will be no negative impact from pit development on groundwater quality owing to the nature of the development, the on-site environmental management processes, the available attenuation capacity within the water table aquifer around the site, and since most water wells around the site are developed within an aquifer that is confined by overlying fine-grained deposits such as clay or hardpan.

Development of the site as an above the water table operation under a Category 3 Application will provide from 20 m to 30 m of available material west of the road allowance between Lots 32 and 33 and about 5 m to 25 m of material east of the road allowance. Within the northwestern portion of the Western Parcel the thickness of sand and gravel resources will range from approximately 14 m to approximately 17 m due to the occurrence of surficial silty deposits (Unit 1). Most of these surficial silty deposits are located within the area not proposed for extraction.

The base of excavation will be 1.5 m above the May 2008 groundwater table, which had an elevation of ± 175 m above sea level (asl) within the central portion of Lots 33 and 32, falling off to below ± 150 m asl in the northwest, ± 155 m asl in the northeast, ± 165 m asl in the southeast, and ± 160 m asl in the southwest. No negative effects to groundwater quality or quantity are predicted.

It is calculated that between about 11 and 14 million cubic metres of suitable material (Units 2 and 3) are available for extraction for the proposed pit design.

There is no notable groundwater contribution to the wetland within the north-central portion of the western portion of the site. Water accumulates within the wetland area during the spring and fall months as a result of surface water runoff, and slowly infiltrates through the underlying silt. As a result, temporary perched groundwater conditions occur

in this area. Pit development will reduce the amount of runoff to the wetland, which will reduce the depth and duration of ponded water (refer to Natural Environment report prepared by AECOM (formerly Gartner Lee Limited((2008) for further details). However, the net infiltration to groundwater in this area will be maintained.

A reduction in surface water runoff on the site will occur, but no negative effects to off-site surface watercourses are predicted as a result of increased infiltration. The contribution of groundwater baseflow to the watercourses will continue.

Based on the findings of the Hydrogeological Study, the above water table pit development and operations will not affect groundwater or surface water resources. A performance monitoring program is outlined in Section 4.0 of the report.

1.0 INTRODUCTION

1.1 BACKGROUND

St. Marys Cement Inc. (Canada), known locally as CBM Aggregates, is proposing to open a sand and gravel pit, to be operated above the water table, on lands referred to as the "Codrington Property", located east of the Village of Codrington, approximately 12 km north of the Town of Brighton as shown on Figure 1. The property encompasses lands to the south of Ontario Hydro power-lines in Parts of Lots 32, 33, and 34, Concession 6, Township of Brighton (site).

Applications under the Aggregate Resources Act (ARA) and its Provincial Standards, as well as the Municipality of Brighton Official Plan and Zoning By-law, are required to open the proposed pit. Jagger Hims Limited has completed this Hydrogeological Study to provide the necessary hydrogeological (groundwater), hydrological (surface water), and geological information as required by the Provincial ARA application and municipal planning applications. The study was prepared essentially in accordance with the guidelines for a Hydrogeological Level 1 Technical Report, in accordance with the Aggregate Resources of Ontario Provincial Standards (AROPS). A Level 1 Report is mandatory for ARA licence applications where extraction is proposed from below the level of the water table. In the case of the Codrington Property, the pit is to be operated above the water table. Accordingly, this study exceeds the normal information requirements necessary under Provincial and municipal approval processes.

As part of this investigation, a number of boreholes were drilled and five monitoring wells installed, designated as BH05-2, BH05-18, BH05-19, BH05-20, and BH06-1. The borehole investigation determined that granular aggregate materials of economically viable quality/quantity exist above the water table at the site, to a maximum depth of approximately 24 to 25 metres below ground surface at the southwest portion of the site,

and approximately 11 metres below ground surface at the southeast portion. The pit operation would remain above the water table at these depths.

1.2 OBJECTIVES AND SCOPE

The primary purpose of the study is to address hydrogeological/hydrological information requirements established by the Municipality and the Province. As such, the objectives are as follows.

- To determine the existing elevations of the groundwater table within the site and to provide the final depth of excavation such that excavation terminates at least 1.5 metres above the water table.
- To identify existing surface water on and surrounding the site, storage and drainage features on the site, points of discharge to surface water, and possible interconnections between surface water and groundwater.
- To assess potential effects of pit excavation activities on local water resources and groundwater use.
- To provide the necessary information to determine any impacts on the natural environment from a hydrogeological/hydrological perspective.

1.3 METHODOLOGY

To obtain site-specific hydrogeologic information regarding the groundwater and surface water systems, possible groundwater and surface water interaction, and input to the pit development, the following activities were undertaken.

- The available topographic and geological mapping for the site area was reviewed and analyzed to interpret the hydrogeological conditions at the site.
- ➤ A historic geological report for the site area was reviewed for preliminary subsurface conditions.
- The MOE water well records for the site and surrounding area were collected and analyzed to determine groundwater depths, geologic profiles, historic water levels, and well yields.
- Two reconnaissance on-site visits were completed to identify the locations for the new boreholes and monitoring wells, and to investigate for seeps, springs, and other components of groundwater and surface water systems.
- Five (5) additional monitoring wells designated as BH05-2, BH05-18, BH05-19, BH05-20, and BH06-1 were installed in five boreholes drilled on the site between May 2005 and March 2006 to permit the establishment of the depth and elevation of the groundwater table, and the direction of groundwater movement. Borehole BH06-2 was drilled and decommissioned after analyses of the geological conditions in the southeast corner of the eastern parcel of the site.
- A survey was undertaken to establish monitoring well elevations to an on-site benchmark of 189.00 metres above sea level (m asl) for the ground surface at BH05-18. In April 2007, the monitoring well elevations were updated using the geodetic information provided by the 43 Degrees North.
- Groundwater levels were measured at monitors BH05-2, BH05-18, BH05-19, and BH05-20 in October 2005, January, March, April, and December 2006, April 2007, and May 2008 during seven monitoring events. In monitor BH06-1 groundwater

levels were measured in March, April, and December 2006, April 2007, and May 2008 during five monitoring events.

A subcatchment analysis and a water balance assessment were completed for the low lying area on the site.

2.0 <u>HYDROGEOLOGIC SETTING</u>

2.1 TOPOGRAPHY AND PHYSIOGRAPHY

The site is located on a hill, which is approximately 2.5 km wide in an east-west direction and slightly longer in the north-south direction. The hill has a flattened top and is approximately 50 m higher than the surrounding sand plain. Regional mapping by Chapman and Putnam (1972), surficial geological mapping (Leyland and Mihychuk, 1984), and the Aggregate Resources Inventory (Rowell, 1997) indicate the presence of lacustrine sand and gravel in the investigated area.

For the convenience of the site description, it is considered that the site consists of two parcels: the Western parcel and the Eastern parcel divided by the road allowance between Lots 32 and 33, as shown in Figure 1.

The maximum elevation on the site is about 204 m asl in the western part of the Western parcel and the minimum elevation is about 180 m asl in the southeastern portion of the Eastern parcel. A low-lying area at an elevation of about 181 m asl is located in the north-central portion of the Western parcel and is identified to be seasonal wetland/pond on the topographic mapping. The northern limit of the site along the Ontario Hydro Easement varies between 180 to 195 m asl, and the southern limit varies between 180 and 195 m asl.

The Codrington area was influenced by a number of glacial and post-glacial events, and the topography is irregular and varied. During the Pleistocene (glacial) Epoch, the area was covered by a succession of ice sheets, which exceeded one kilometre in thickness. During the retreat and melting of the ice sheets, the ice split into several ice lobes, which behaved semi-independently. A northern ice lobe stood in the Rice Lake – Sterling area, and the Lake Ontario lobe was centred in the Lake Ontario basin. The Oak Ridges Moraine was formed between these two lobes, and the moraine is a major glacial and physiographic feature to the west of the Brighton area toward Toronto. Brighton is near the eastern extremity of the Oak Ridges Moraine, although the feature is poorly developed in this area and was eroded into several disconnected fragments.

The Oak Ridges Moraine and the drumlinized till plains to the north and to the south of the moraine were subjected to a variety of pro-glacial and post-glacial influences. During the waning of the ice, a number of glacio-fluvial ice-contact features, such as eskers and kames were deposited. Meltwater that flowed generally southward from the ice front often eroded previously existing landforms and/or deposited surficial outwash sand with occasional gravel. The site itself is not in the Oak Ridges Moraine physiographic region or the Oak Ridges Moraine Conservation Plan Area (ORMCPA).

A series of high level pro-glacial lakes existed in the area after the deposition of the major glacial landforms. The lakes formed adjacent to the ice lobes and numerous shorelines and sand plains were deposited at that time in the Brighton area. The lake deposits commonly were developed on, and overlie, previously existing deposits.

Lands within the study area are primarily undeveloped and consist of bush, sand/gravel highlands, and some farmlands.

2.2 GEOLOGY

2.2.1 Regional Geology

The available geological information for the Codrington area indicates that the surficial materials are lacustrine origin. These materials are several metres in thickness and they overlie some type of older deposits. Leyland and Mihychuk (1984) noted the presence of silt to sand till over much of the southern portion of the deposit, and this suggests that the Codrington hill is one of several flat-topped till mounds in the area.

The actual soil stratification was interpreted from the data obtained from MOE water well records and Jagger Hims Limited boreholes, which are shown on Figure 2. The regional cross sections A-A' and B-B', presented on Figures 3 and 4, reflect the regional geology. The site is located on a high area of land with near surface deposits of silt, sand, and gravel. Deeper units of fine-grained soil (clay, silt, and hardpan) are present and also occur near surface within the surrounding lower lying area. Surficial sand deposits also occur in the lower lying area. Bedrock was detected north of the site at a depth of about 12 m below ground surface, which corresponds to an elevation of about 115 m asl.

2.2.2 Local Geology

Thirty-seven test pits and seventeen boreholes were completed on the site in early 2005. Three additional boreholes were completed in late 2005 and two more in early 2006 (for total of 22 boreholes) to investigate local geological conditions. The interpretation of local geology suggests that the Codrington hill is an ice-contact or kame feature whose surface was modified by the later lacustrine events in the area. The 2005 and 2006 drilling results support the interpretation that Codrington hill is an ice-contact glaciofluvial deposit of significant thickness. The locations of the boreholes advanced during both drilling programs are shown on the Site Plan, Figure 5. The results of the drilling are detailed in the appended borehole logs of Appendix A and are summarized on Figures 6, 7, and 8.

The main finding of the drilling is that there are substantial amounts of sand and gravelly sand in the subsurface beneath the Codrington Property and that a large amount of this material is above the water table. A detailed analysis of the borehole results allows for the grouping of the material encountered into three major units.

Unit 1

Unit 1 includes silt till and silty fine sand that are generally in the order of about 5 m to 8 m thick, but were detected to be at least 11.9 m deep at BH05-15 and 16.8 m deep at BH05-16. This unit is prominent near surface in boreholes BH05-6, BH05-8, BH05-9, BH05-10, BH05-12, BH05-13, BH05-15, BH05-16, BH05-19, and BH05-20. A surficial 1.5 m thick portion of Unit 1 is located at BH05-4.

Unit 2

Unit 2 is the main sand and gravel unit present on the site. The unit is prominent at surface or below Unit 1 in the southern and eastern portions of the site. The material of Unit 2 is variable in texture and commonly ranges from fine to medium sand with some (20%) gravel to sand and gravel in approximately equal proportions. The gravel-rich areas appear as lenses or beds within the sand, and the gravel content is variable. The unit reaches a confirmed maximum thickness of 25 m in the south-central and eastern portion of the site near boreholes BH05-4, BH05-5, BH05-6, BH05-7, BH06-1, and BH06-2. There are several small inclusions of till and silt within Unit 2, which support the idea that much of this unit is ice-contact in origin. However, the upper few metres of material were likely wave-washed during the existence of Lake Iroquois in the area.

Unit 3

Unit 3 is generally fine to medium sand with an occasional lens (e.g. BH05-13) of coarser material. The unit is present at depth beneath much of the site and is generally regarded as marginal for use as aggregate due to its fine-grained texture and lack of gravel. Unit 3 is transitional with Unit 2 and essentially represents the gravel-poor phase of the combined unit.

Many of the boreholes encountered difficult drilling at the 25 m to 35 m depth. Boulders and/or a possible cemented layer were identified in several boreholes at the depth of approximately 30 m, and saturated sand was also encountered at a similar depth.

Two boreholes were advanced near the low-lying area in the north-central portion of the Western parcel of the site. BH05-19 was advanced to a depth of 29.6 m and intersected a shallow silt unit (Unit 1) from 0.6 to 8.2 m below ground surface. Owing to the potential for the silt unit to contain a perched water table, a second borehole BH05-20 was advanced within the southern portion of the low-lying area to a depth of 5.1 m and was completed as a standpipe monitoring well.

2.3 GROUNDWATER SETTING

2.3.1 Regional Groundwater Setting

Most of the water wells are located around the high area of land at a distance of more than 1 km from the site. The Ministry of the Environment (MOE) water well record locations are shown in Figure 2 and listed in Tables A-1 and A-2, Appendix A. A well record for the recently drilled water well located west of the site boundary is also presented in Appendix A. Two regional hydrogeological cross-sections A-A' and B-B' are presented in Figure 3 and Figure 4.

Based on the MOE water well records, most water wells are drilled wells that are developed within deep sand and/or gravel deposits greater than 15 m below ground surface. Some shallower water wells and dug wells are present. Around the high area of land, most water wells are developed within an aquifer that is confined by overlying fine-grained material such as clay or hardpan. It is anticipated that the clay identified in the well records is dominantly silt with different proportions of clay, and may be a fine-grained till.

The two well records for water supply wells in the high area of land (272 and A027288) indicate deep wells to about 40 m below ground surface. A027288 indicates confining layers of fine-grained material, with a perched water table at about 32 m below ground surface.

Groundwater levels in the water wells indicate higher groundwater elevations within the high land, with lower groundwater levels in water wells in the surrounding lower lying areas. Therefore, as expected, regional groundwater is inferred to move in a radial pattern from the high land toward the surrounding lower lying areas. Thus, the high land represents a regional groundwater recharge area.

Based on available data, local groundwater uses are for domestic purposes and some limited uses for livestock watering.

2.3.2 Site Hydrogeology

Groundwater levels were measured in the on-site monitoring wells BH05-2, BH05-18, BH05-19, and BH05-20 in October 2005, in January, March, April, and December 2006, in April 2007, and in May 2008. In monitor BH06-1, groundwater levels were measured in March, April, December 2006, in April 2007, and in May 2008. Monitors locations are shown on Figure 5. Monitor construction details are presented in Table B-1 and groundwater elevations are presented in Table B-2, Appendix B.

Groundwater levels within the deep monitoring wells in average fluctuated less than 0.75 m from October 4, 2005 to May 9, 2008. Considering that infiltration to the water table will naturally vary between the fall, winter, and spring, it is interpreted that the permeable soil permits the rapid dissipation of infiltration. Thus, the late spring water table conditions observed in May 2008 may be considered to represent the maximum water table elevation for the site at most locations. At BH05-18, the maximum water table elevation occurred in April 2007.

Figure 9 presents the maximum water table configuration observed for May 2008. As presented, the groundwater table is inferred to be highest in elevation with the central portion of the site below the area of high surface topography and where sand occurs near surface. Within the northwestern portion of the site, the fine-grained surficial material (silt and silty fine sand) prevents the rapid infiltration of water to the water table and thus prevents the establishment of high water table levels. The direction of groundwater movement is outward from the groundwater high toward the north, south, east, and west. As expected, no groundwater seeps or springs were identified on the site.

A seasonal perched groundwater table was detected near the wetland/pond area within the north-central portion of the Western parcel of the site at BH05-20. In October 2005, a water table was not detected, but from January 2006 through May 2008 the perched water table was within 0.5 m of ground surface. It is interpreted that the perched water table is formed as a result of the slow downward movement of groundwater through the underlying clayey silt. As shown in Figure 6, the clayey silt (Unit 1) is underdrained by the deeper unconfined water table.

Based on the water table configuration and the surrounding low areas, it is inferred that vertical hydraulic gradients are downward and the site is located in a groundwater recharge area.

2.4 SURFACE WATER

On a regional basis, there are few surface watercourses located within two kilometres of the site. One watercourse is Cold Creek, which is about 1 km south of the site and flows in an easterly direction. A tributary of Marsh Creek is located about 1 km west of the site and flows in a northerly direction toward Murray Marsh, which is located about 2 km northeast of the site. Tributaries of Marsh Creek and Murray Marsh are located within about 500 m east of the site. A permanent watercourse was identified about 50 m south from the southeast corner of the site, which slopes in an easterly direction. Based on the water table

elevation in this area as presented in Figure 9, there is a groundwater baseflow component to this watercourse. The groundwater also contributes to baseflow in watercourses located further removed from the site, such as Cold Creek and Marsh Creek.

There was no evidence of surface water on the site during September to November 2005, and from March 2006 to May 2008, except within the wetland area within the north-central portion of the Western parcel. The low-lying area contained some seasonal water accumulation of about 0.2 m depth in March 2006 and about 0.5 m in December 2006, April 2007, and May 2008 as a result of snowmelt and overland surface water runoff from the surrounding areas of higher topography as well as poor downward drainage due to the underlying lower permeability silt. From January 2006 through May 2008 the monitoring well at BH05-20 detected a perched water table within about half a metre below the ground surface. The highest level of perched water was detected at BH05-20 in May 2008, when the water table was within about 0.1 m from the ground surface.

2.5 CLIMATIC WATER BUDGET

The water balance for the study area was estimated using available climatic data from the on-line resources provided by Environmental Canada and the Ministry of the Environment (MOE) infiltration guidelines. The climatic water budget data from the local climatic station at Belleville are summarized in Tables C-1 and C-2, Appendix C. Based on the normal data for 1971 to 2000, the annual precipitation averages about 891.8 mm (mm/a). Considering available evapotranspiration of about 533.2 mm/a, the precipitation available for runoff or infiltration is about 358.6 mm/a.

As expected, a calculated water surplus occurs during the winter, spring, and fall months, with a water deficit during the summer months. It should be noted that the majority of water surplus in the winter accumulates as snow. Snowmelt during the spring results in the runoff or infiltration of precipitation that is effectively equivalent to the winter and spring water surplus.

2.6 SUBCATCHMENT ANALYSIS

To assess the contribution of precipitation to groundwater and surface water, and to obtain the data required for an environmental impact assessment of the proposed pit development, a subcatchment analysis was performed for the site.

The site was partitioned into three catchment areas for: 1) the on-site wetland, 2) Cold Creek, and 3) Marsh Creek. Each catchment area was then subdivided into subcatchment areas based on the proposed pit excavation boundaries and buffers as shown in Figure 10. The infiltration and runoff rates were calculated for each of these subcatchments. A summary of the water balance for subcatchments under pre-development and post-development conditions is provided in Table 1.

The proposed site development will shift portions of the surface water flow divides for local subcatchments. The following subcatchments will change drainage areas to which they contribute; unlisted areas will not change.

SUBCATCHMENT AREA	PRE-DEVELOPMENT DRAINAGE	POST-DEVELOPMENT DRAINAGE DIRECTION
1A	Wetland/Pond	Groundwater
1B	Wetland/Pond	Groundwater*
1C	Wetland/Pond	Groundwater*
1D	Wetland/Pond	Groundwater*
1E	Wetland/Pond	Groundwater
1G	Wetland/Pond	Groundwater*
2A	Cold Creek	Groundwater
3A	Marsh Creek	Groundwater
3E	Marsh Creek	Groundwater
3G	Marsh Creek	Groundwater

NOTE: * indicates that the runoff component will be toward the excavation and will infiltrate as groundwater within the excavation.

Infiltration and runoff for each subcatchment was calculated using the method of Table 2 in the Hydrogeologic Information Requirements (MOE, 1995), with some adjustments for site conditions. Runoff was calculated as the difference between moisture surplus and infiltration.

The following are detailed comments on the infiltration calculations that were completed for the site.

- Input values for Table 1 subfactors are based on available information for soil and groundwater conditions. For subcatchments without direct subsurface information, conditions were inferred from the nearest borehole/monitoring well.
- The subcatchment areas were calculated based on the indicated boundaries shown in Figure 10. Water balance calculations were completed for above groundwater table extraction on the area of development.
- The moisture surplus used in the calculations was derived from the long-term climatic average conditions, based on records between 1971 and 2000. Monthly evapotranspiration values were calculated using the Thornthwaite and Mather method (1957) that included a daylight correction for latitude.
- For the wetland/pond an infiltration factor of 1 was considered for direct precipitation and runoff as water will accumulate and eventually infiltrate into the subsurface and contribute to groundwater. Open water evaporation was assumed to be similar to the calculated evapotranspiration.
- The area covered with wetland was assumed to provide a similar infiltration factor for pre-development and post-development conditions.

A summary of the site water balance for pre-development and post-development conditions is provided in Table 1. The primary data for the site water balance calculations is shown in Table C-3, Appendix C.

For the majority of the site the infiltration rate varied between 70% and 80% of the water surplus for an infiltration coefficient of 0.7 to 0.8. Therefore, a runoff coefficient of between 0.2 and 0.3 was estimated for the site for pre-development conditions. Thus, an annual runoff between 72 and 108 mm/a and an annual infiltration between 251 and 287 mm/a are reasonable. One exception is for the wetland area within the north-central portion of the Western parcel of the site, where an infiltration rate of 100% was estimated. Due to the site topography in this area, the water surplus that accumulates in the wetland area eventually infiltrates into the underlaying soil which results in localized seasonal perched groundwater conditions.

3.0 IMPACT ASSESSMENT

3.1 **PROPOSED OPERATIONS**

CBM Aggregates proposes to operate the pit as an above the water table operation. In accordance with the ARA Provincial Standards, this operation requires that the base of the pit must be greater than 1.5 m above the water table. As noted in Section 2.3, water table levels in average fluctuated by less than 0.75 m from October 2005 through May 2008, and the late spring water table conditions observed in May 2008 may be considered to represent the maximum water table elevation for the site at most locations. At BH05-18 the maximum water table elevation occurred in April 2007.

Groundwater monitors BH05-18 and BH05-19 indicate that the depth to the water table within the southwestern portion of the site is between about 23.9 to 25.2 m below ground surface. Within the southeastern portion of the site in the vicinity of BH05-2 the water

table is about 10.0 m below ground surface, while within the eastern portion of the site in the vicinity of BH06-1 the water table is about 7.0 m below ground surface.

The following table provides an assessment of the extractable material at the site with respect to the above water table criterion. It is noted that the extractable material includes material from Units 1, 2, and 3 as defined in Section 2.2. Depending on the elevation of surface topography and the water table, there are localized areas of greater or lesser extractable material.

COMPARISON OF WATER TABLE AND EXTRACTABLE MATERIAL

MONITOR DESIGNATION	DEPTH TO WATER TABLE (m bgl)	SOIL THICKNESS ABOVE WATER TABLE (m bgl)	THICKNESS OF EXTRACTABLE MATERIAL (m)
BH05-2	10.0	10.0	8.5
BH05-18	23.9	23.9	22.4
BH05-19	25.2	25.2	23.7
BH06-1	7.0	7.0	5.5

NOTES:

1) 'm bgl' indicates metres below ground level.

2) 'm' indicates metres.

3) Water table depth based on maximum elevations (April 2007 or May 2008).

4) ARA/Standards Criterion is a base excavation 1.5 m above water table.

In summary, the greatest thickness of extractable material occurs in the area of higher surface topography west of the road allowance between Lots 32 and 33 (Western parcel). However, it is noted that northwest of BH05-9 the surficial unit of silt to silty fine sand (Unit 1) ranges in thickness from about 4.6 m to 8.2 m, with greater than 11.9 to 16.8 m of Unit 1 at BH05-15 and BH05-16, respectively. See Figure 5 for location details.

Based on the May 2008 water table configuration presented in Figure 9, the pit average base elevation will be about 177.1 m asl (175.6 m asl + 1.5 m) within the central portion of the site and may vary along the site perimeter as detailed in the following table. It is noted that the pit base elevation presented for BH05-18 is based on the April 2007 data, which recorded the maximum water table elevation of all the monitoring events.

MONITOR	GROUND SURFACE ELEVATION	PIT BASE ELEVATION	
DESIGNATION	(m asl)	(m asl)	
BH05-2	184.8	176.3	
BH05-18	191.0	168.6	
BH05-19	185.0	161.3	
BH06-1	182.6	177.1	

Based on the data obtained during the subsurface investigations and groundwater monitoring program, the quantity of the aggregate resources available for extraction was calculated. The calculations were completed for the two scenarios: Scenario I with a vertical slope of extraction, and Scenario II with extraction with a slope ratio of 3:1 (horizontal : vertical). In both scenarios the volumes of resources available for extraction were calculated with consideration of the three phases of the pit development. The calculations results are summarized below.

SCENADIO #	MATERIAL VOLUME (m ³)			
SCENARIO #	PHASE I	PHASE II	PHASE III	TOTAL
Scenario I: Vertical Slopes	6,398,433	3,898,449	10,235,889	20,532,771
Topsoil and silt (Unit 1)	1,147,203	920,484	4,125,169	6,192,856
Sand and gravel (Units 2 and 3)	5,251,230	2,977,965	6,110,720	14,339,915
Scenario II: Slopes at 3:1	4,816,017	2,269,863	8,160,669	15,246,549
Topsoil and silt (Unit 1)	652,698	557,442	3,048,921	4,259,061
Sand and gravel (Units 2 and 3)	4,163,319	1,712,421	5,111,748	10,987,488

In the event that material washing operations are considered as part of the site operations, Section 3.3 provides a summary of surface water available for on-site storage. If groundwater is required to supplement the surface water storage, a Permit To Take Water may be required.

A minor groundwater supply will be required for dust control and for periodic watering of trees to be planted as part of the site rehabilitation program. As the predicted maximum water requirement will not exceed 50,000 L/day, a Permit To Take Water will not be required. Water will either be obtained from an off-site source or from an on-site water

supply well located within the northern portion of the Western parcel of the site, which is not proposed for extraction.

3.2 GROUNDWATER ASSESSMENT

According to common industry findings for above water table pit development and based on Jagger Hims Limited's 20 years of experience in extensive groundwater monitoring at similar pits, above water table extraction is not known to negatively affect groundwater resources. However, to meet and exceed the Provincial requirements as established by the ARA Provincial Standards, a detailed groundwater assessment was completed to evaluate the possible effects of the above water table extraction on groundwater resources.

Based on the available area for pit development south of the Ontario Hydro Easement and estimated setbacks, a pit area of about 81 ha is estimated. The total infiltration volume for the property in pre-development conditions is about 284,805 m³/a, with about 94,126 m³/a of runoff. Development of the pit will prevent runoff within the pit area and some adjacent subcatchment areas, and re-direct the runoff to infiltration through the permeable sandy soil. Therefore, the infiltration volume in post-development conditions will be about 356,954 m³/a. As such, the post-development conditions will be characterized with an increase in infiltration to the groundwater table of about 72,162 m³/a.

The predicted increase in infiltration of water surplus to the groundwater table will maintain the groundwater recharge characteristics of the site. It is predicted that the predevelopment water table high within the central portion of the site will be maintained and may increase by about 0.1 m to 0.2 m upon completion of the excavation as a result of the increase in infiltration. As such, shallow groundwater will continue to move from the site in a radial direction toward the low-lying areas that surround the site. Downward hydraulic gradients through the underlying low permeable units will maintain the quantity of water currently available to local water wells around the site. Based on groundwater information collected from October 2005 to May 2008, there is no notable shallow groundwater contribution to the wetland area within the north-central portion of the Western parcel. Water accumulates within the low-lying area during the spring and fall months as a result of surface water runoff, and slowly infiltrates through the underlying silt.

Water quality impacts are not anticipated and operation of the pit in accordance with prescribed conditions and Technical Standards and Safety Authority (TSSA) requirements will protect water quality. The sandy soil and attenuation capacity around the site will also prevent detectable changes in suspended solids or temperature within the shallow groundwater beyond the 120 m zone around the property as shown in Figure 10.

The watercourse southeast of the property is about 90 m from the edge of the excavation. Considering the lateral hydraulic gradient (0.017 m/m), a range of reasonable bulk hydraulic conductivities for the soil $(10^{-4} \text{ to } 10^{-3} \text{ m/s})$, and a soil porosity of 30%, groundwater movement from the excavation to the watercourse would take about 18 to 180 days, which should provide sufficient time for the infiltration to equilibrate to normal groundwater temperatures. In addition, the low permeable units that protect the deeper sand and gravel aquifers will not be compromised by the pit development.

In summary, it is predicted that the development of a pit on the site will not result in adverse effects to the local groundwater quantity or quality. Groundwater monitoring is recommended in Section 4.0 of this report to confirm acceptable groundwater conditions, and this monitoring program will be included on the ARA Site Plan for the proposed pit.

3.2.1 Effects on Local Water Wells

The results contained in Section 3.2 indicate that the regional groundwater table will not be adversely affected by pit excavation. This assessment is consistent with the research

findings published by the Ministry of Natural Resources in the document entitled Applied Research On Source Water Protection in the Aggregate Industry.

The pit excavation has no predicted negative effects on groundwater quantity or quality. In fact, it will increase the overall recharge to the aquifer. As such, there will be no negative effects of the proposed excavation on the local groundwater users. Correspondingly, the closest water well, which is located downgradient from the western site boundary at a distance of about 20 m, will not be negatively affected by the proposed pit development.

3.3 SURFACE WATER ASSESSMENT

Considering the method of extraction above the groundwater table, the plan to keep a "no extraction zone" in the northwest corner of the site, the distance to the nearest surface watercourses, and a predicted increase in groundwater recharge, no negative effects to local watercourses are expected from the pit operations.

A reduction in runoff on the site and toward the site boundaries is predicted. The runoff to the on-site wetland located within the north-central portion of the Western parcel is predicted to be about 77% less than pre-development conditions. As a result, the depth and duration of the ponded water in the wetland will be reduced. However, as the wetland represents a groundwater recharge feature and the reduced runoff corresponds to an increase in infiltration, no negative effects to groundwater quantity or quality are predicted in this area. Impacts on the wetland are further reviewed in the Natural Environment report prepared by AECON (formerly Gartner Lee Limited) (2008).

Runoff from the site toward Cold Creek will decrease by about 80% with the proposed extraction area. This runoff reduction is minor compared to the overall watershed area for Cold Creek and considering the surficial sand and gravel south of the site where most runoff will infiltrate into the groundwater. In addition, the corresponding increase in

infiltration will enhance the southerly groundwater movement and the baseflow contribution to the creek.

Within the northern and eastern portions of the site, the component of runoff toward Marsh Creek will decrease by about 70%, while the overall infiltration to groundwater will increase. As noted above, the resultant groundwater baseflow to the local watercourses compensate for the reduced runoff.

The volume of surface water available for storage and use for material washing as part of site operations will depend on the surface area and design of on-site storage/settlement ponds. The permeability of the sandy soil requires that the ponds be designed with a low permeable base of on-site silty soil. In addition, the settlement of fines will enhance the retention capability of the ponds. Assuming that evaporation from the ponds will be similar to the estimated evapotranspiration rates, a lined pond should provide water at a rate of about $0.36 \text{ m}^3/\text{a/m}^2$ of pond area. Most water accumulation in the ponds will occur during the spring months.

No off-site discharge of water from the storage/settlement ponds will be required. Excess water may be directed to the wetland/pond for infiltration to the groundwater table.

4.0 <u>PERFORMANCE MONITORING PROGRAM</u>

Development of the pit as an above the water table operation will not have a negative effect on local groundwater or surface water resources. However, it is recommended that the following performance monitoring program be implemented to confirm acceptable conditions and to provide input to contingency measures, if required.

Considering the proposed extraction area, monitoring wells BH05-19 and BH05-20 should be decommissioned in accordance with the regulatory requirements.

The performance monitoring program should include the following.

- Groundwater Level Monitoring Complete at BH05-2, BH05-18, and BH06-1 on a quarterly basis over the calendar year.
- Baseline Groundwater Quality Monitoring Complete one monitoring event at BH05-2, BH05-18, and BH06-1 prior to extraction for the following parameters: pH, conductivity, turbidity, temperature, and total dissolved solids.
- Annual Reporting Prepare an annual monitoring report by March 31 of each year to summarize the monitoring results of the preceding year. The report should document complaints and responses.
- Groundwater quality sampling should be completed once, prior to commencement of pit operations. The groundwater level monitoring should be completed annually on a quarterly basis.

It is predicted that an above the water table pit operation will have no negative affects on groundwater and surface water resources.

4.1 CONTINGENCY MEASURES

If groundwater levels at BH05-2, BH05-18, and BH06-1 decrease by 2 m relative to baseline conditions, a detailed review of data collected for the site to determine the cause should be completed.

If the water level decrease is a result of site operations, increase the scope of the performance monitoring program to include residential wells within 100 m of the site and the watercourse southeast of the site. Monitoring should include annual quality tests for the baseline parameters and quarterly levels.

If pit operations are determined to negatively affect groundwater or surface water resources, the following contingency measures should be implemented.

- 1. Interference with acceptable quality or quantity of water in a water well should result in provision of an acceptable water supply by either installation of a new water well or a suitable alternative.
- 2. Negative effects on the watercourse should be remediated by changes in site operations or through site rehabilitation.

5.0 <u>CONCLUSIONS AND RECOMMENDATIONS</u>

The results of this Hydrogeologic Study indicate that no negative effects to the groundwater and surface water regimes are predicted as summarized below.

- A sand and gravel unit (Unit 2) occurs across the southern portion of the site and achieves a confirmed maximum thickness of about 25 m within the south-central portion of the site. The underlying sand unit (Unit 3) contains less gravel. Within the northwest portion of the site a silt to silty sand unit (Unit 1) occurs at surface and is generally 5 m to 8 m in thickness, but was detected to a depth of about 17 m at one borehole location.
- The wetland within the north-central portion of the Western parcel of the site is located in an area with a surficial silt layer (Unit 1) that is about 8 m in thickness, but thickens toward the northwest.
- The site is located within a high area of land that forms a regional recharge area for dominantly confined aquifers in the surrounding lower lying areas. Most water wells are developed in confined aquifers at a depth greater than 15 m below ground

surface. The quantity of water available for domestic water supply wells will not be negatively affected by the pit development as the recharge to the aquifer developed by the local water wells is predicted to increase. In addition, there will be no negative impact from pit development on groundwater quality owing to the nature of the development, the on-site environmental management processes, and the available attenuation capacity within the water table aquifer around the site. Most water wells around the site are developed within an aquifer that is confined by overlying fine-grained deposits such as clay or hardpan.

- Development of the site as an above the water table operation under a Category 3 Application will provide from 20 m to 30 m of available material west of the road allowance between Lots 32 and 33 (Western parcel) and about 5 m to 25 m of material east of the road allowance (Eastern parcel). Within the northwestern portion of the Western parcel the thickness of sand and gravel resources will range from approximately 14 m to approximately 17 m due to the occurrence of surficial silty deposits (Unit 1). Most of these surficial silty deposits are located within the area not proposed for extraction.
- It is calculated that between about 11 and 14 million cubic metres of suitable material (Units 2 and 3) are available for extraction for the proposed pit design.
- The base of excavation will be 1.5 m above the May 2008 groundwater table, which had an elevation of ±175 m above sea level (asl) within the central portion of Lots 33 and 32, falling off to below ±150 m asl in the northwest, ±155 m asl in the northeast, ±165 m asl in the southeast, and ± 160 m asl in the southwest.
- Pit development will increase the groundwater recharge in the area. No negative effects to groundwater quality or quantity are predicted. Similarly, water wells in the area will not be negatively affected by the pit development.

- There is no notable groundwater contribution to the wetland within the Western parcel of site. Water accumulates within the wetland during the spring and fall months as a result of surface water runoff, and slowly infiltrates through the underlaying silt. As a result, temporary perched groundwater conditions occur in this area. Pit development will reduce the amount of runoff to the wetland, which will reduce the depth and duration of ponded water. However, the net infiltration to groundwater in this area will be maintained.
- A reduction in surface water runoff on the site will occur, but no effects to off-site surface watercourses are predicted as a result of increased infiltration. The contribution of groundwater baseflow to the watercourses will continue.

The following recommendation is provided for consideration.

The performance monitoring program should be implemented as outlined in Section 4.0.

Yours truly, JAGGER HIMS LIMITED

NOTES:

1) Infiltration rate derived from Table 2 of MOE (1995).
 2) Woodland and grass/farmland areas based on 2007 site conditions.

.

3) "m³/a" means cubic metres per annum.

4) Totals may vary due to rounding.

NOTES:

1) Infiltration rate derived from Table 2 of MOE (1995).

2) Woodland and grass/farmland areas based on 2007 site conditions.

3) "m³/a" means cubic metres per annum.

4) Compensation amount=[infiltration under pre-development conditions]-

-[infiltration during post-development conditions]. 5) * indicates runoff will be toward excavation and become part of groundwater.

6) Totals may vary due to rounding.

BOREHOLE LOG EXPLANATION FORM

This explanatory section provides the background to assist in the use of the borehole logs. Each of the headings used on the borehole log, is briefly explained.

DEPTH

This column gives the depth of interpreted geologic contacts in metres below ground surface.

STRATIGRAPHIC DESCRIPTION

This column gives a description of the soil based on a tactile examination of the samples and/or laboratory test results. Each stratum is described according to the following classification and terminology.

<u>Soil Clas</u>	sification *	Terminology	Propertion
Clay	<0.002 mm		
Silt	0.002 to 0.06 mm	"trace" (eg. trace sand)	<10%
Sand	0.06 to 2 mm	"some" (eg. some sand)	10% - 20%
Gravel	2 to 60 mm	adjective (eg. sandy)	20% - 35%
Cobbles	60 to 200 mm	"and" (eg. and sand)	35% - 50%
Boulders	>200 mm	noun (cg. sand)	>50%

* Extension of MIT Classification system unless otherwise noted.

The use of the geologic term "till" implies that both disseminated coarser grained (sand, gravel, cobbles or boulders) particles and finer grained (silt and clay) particles may occur within the described matrix.

The compactness of cohesionless soils and the consistency of cohesive soils are defined by the following:

<u>COHESI</u>	IONLESS SOIL	<u>COHESIVE SOIL</u>			
Compactness	Standard Penetration Resistance "N", Blows / 0.3 m	Consistency	Standard Penetration Resistance "N", Blows / 0.3 m		
Very Loose	0 to 4	Very Soft	0 to 2		
Loose	4 to 10	Soft	2 to 4		
Compact	10 to 30	Firm	4 to 8		
Dense	30 to 50	Stiff	8 to 15		
Very Dense	Over 50	Very Stiff	15 to 30		
•		Hard	Over 30		

The moisture conditions of cohesionless and cohesive soils are defined as follows.

Drier Then Diestie Limit	
PL - About Plastic Limit TPL - Wetter Than Plastic Limit WTPL - Wetter Than Plastic Limit	t a Timit
2	TL - About Plastic Limit TPL - Wetter Than Plastic Limit WTPL - Much Wetter Than Plastic

STRATIGRAPHY

Symbols may be used to pictorially identify the interpreted stratigraphy of the soil and rock strata.

MONITOR DETAILS

This column shows the position and designation of standpipe and/or piezometer ground water monitors installed in the borehole. Also the water level may be shown for the date indicated.

Where monitors are placed in separate boreholes, these are shown individually in the "Monitor Details" column. Otherwise, monitors are in the same borehole. For further data regarding seals, screens, etc., the reader is referred to the summary of monitor details table.

SAMPLE

These columns describe the sample type and number, the "N" value, the water content, the percentage recovery, and Rock Quality Designation (RQD), of each sample obtained from the borehole where applicable. The information is recorded at the approximate depth at which the sample was obtained. The legend for sample type is explained below.

SS	=	Split Sp	oon	G\$ =	Grab Sample
ST	=	Thin Wa	illed Shelby Tube	CS =	Channel Sample
AS	=	Auger F	light Sample	WS =	Wash Sample
CC	=	Continu	ous Core	RC =	Rock Core
% R	ecov	ery =	Length of Core Re Total Leng	eovered Per Ru	<u>n</u> x 100

Where rock drilling was carried out, the term RQD (Rock Quality Designation) is used. The RQD is an indirect measure of the number of fractures and soundness of the rock mass. It is obtained from the rock cores by summing the length of core recovered, counting only those pieces of sound core that are 100 mm or more in length. The RQD value is expressed as a percentage and is the ratio of the summed core lengths to the total length of core run. The classification based on the RQD value is given below.

RQD Classification	<u>RQD (%)</u>
Very poor quality	< 25
Poor quality	25 - 50
Fair quality	50 - 75
Good quality	75 - 90
Excellent quality	90 - 100

TEST DATA

The central section of the log provides graphs which are used to plot selected field and laboratory test results at the depth at which they were carried out. The plotting scales are shown at the head of the column.

Dynamic Penetration Resistance - The number of blows required to advance a 51 mm diameter, 60° steel cone fitted to the end of 45 mm OD drill rods, 0.3 m into the subsoil. The cone is driven with a 63.5 kg hammer over a fall of 750 mm.

Standard Penetration Resistance - Standard Penetration Test (SPT) "N" Value - The number of blows required to advance a 51 mm diameter standard split-spoon sampler 300 mm into the subsoil, driven by means of a 63.5 kg hammer falling freely a distance of 750 mm. In cases where the split spoon does not penetrate 300 mm, the number of blows over the distance of actual penetration in millimetres is shown as $\frac{xBlows}{x}$

Water Content - The ratio of the mass of water to the mass of oven-dry solids in the soil expressed as a percentage.

mm

- W_P Plastic Limit of a fine-grained soil expressed as a percentage as determined from the Atterberg Limit Test.
- W_L Liquid Limit of a fine-grained soil expressed as a percentage as determined from the Atterberg Limit Test.

REMARKS

The last column describes pertinent drilling details, field observations and/or provides an indication of other field or laboratory tests that were performed.

NOTES:

1) Water budget adjusted for latitude and daylight.

mm

358.6

TOTAL MOISTURE SURPLUS

mm

248.3

Total Water Surplus

2) (°C) - Represents calculated mean of daily temperatures for the month.

3) Data from the Belleville Climatological Station located at latitude 44° 9' N, longitude 77° 23' W.

4) Total Water Surplus (Thornthwaite, 1948) is calculated as total precipitation minus adjusted potential evapotranspiration.

5) Total Moisture Surplus (Thornthwaite and Mather, 1957) is calculated as total precipitation minus actual potential evapotranspiration.
